Anechoic chamber

An anechoic chamber is an artificially created space designed to replicate the characteristics of a free

field. It is primarily used for measuring the properties of equipment.

An anechoic chamber is an environment that minimizes acoustic reflections originating from the [surroundings](#), creating a nearly entirely sound-absorbing state. Anechoic chambers are mainly utilized for purposes such as acoustic research, sound measurements, product testing, and development.

These chambers offer an environment where the characteristics of acoustic signals can be precisely measured and analyzed. They are employed for acoustic research and measurement, allowing for testing and analysis of components like [speakers](#), microphones, and acoustic equipment. Moreover, they enable the investigation of aspects such as sound radiation characteristics, acoustic impulse responses, and acoustic feature analysis.

Anechoic chambers are vital spaces that exclude acoustic reflections and interference encountered in real-world environments, facilitating accurate acoustic measurements and research.
